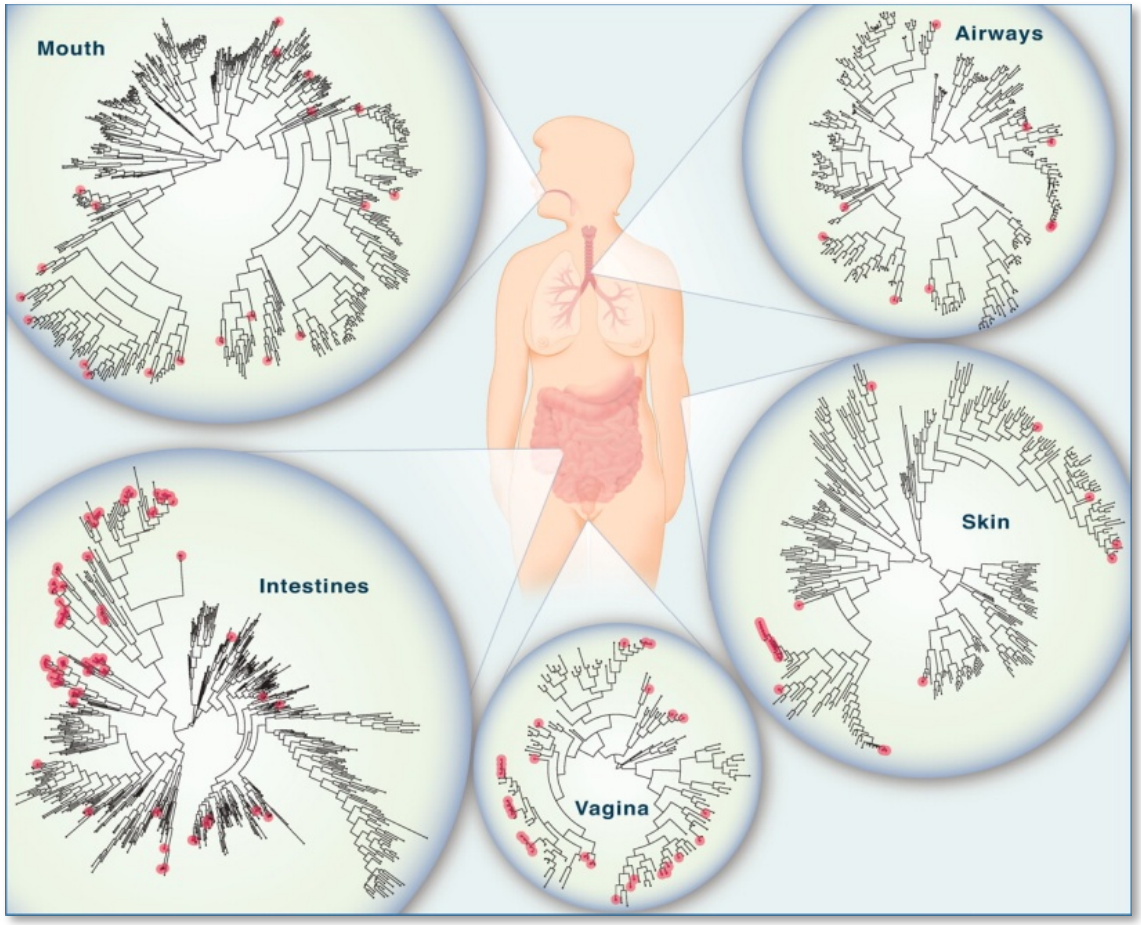
Pro-inflammatory Response to Food Antigens - CID

The human microbiome



- The human gut harbors 10^{11}-10^{12} bacteria per gram colonic content (>10^{14} total bacteria)
- Total bacteria outnumber human cells 10:1
- Total bacterial genes outnumber human genes >150:1
- >10,000 different species of bacteria are resident in the human intestinal microbiota (400-500 per person)

Abstract

Celiac disease (CD) is a unique autoimmune disorder in which the genetic factors (DQ2/DQ8) and the environmental trigger (gluten) are known and necessary but not sufficient for its development. Other environmental components contributing to CD are poorly understood. Studies suggest that aspects of gluten intake might influence the risk of CD occurrence and timing of its onset, i.e., the amount and quality of ingested gluten, together with the pattern of infant feeding and the age at which gluten is introduced in the diet. In this study, we hypothesize that the intestinal microbiota as a whole rather than specific infections dictates the switch from tolerance to immune response in genetically susceptible individuals. Using a sample of infants genetically at risk of CD, we characterized the longitudinal changes in the microbial communities that colonize infants from birth to 24 months and the impact of two patterns of gluten introduction (early vs. late) on the gut microbiota and metabolome, and the switch from gluten tolerance to immune response, including onset of CD autoimmunity. We show that infants genetically susceptible to CD who are exposed to gluten early mount an immune

The Real Story of Our Genetic Complexity:

We Inherit two Parallel Genomes

Human Genome:

Inherited from both parents, stable, never change in its composition

Microbiome:

Inherited from the mother, extremely dynamic, changes from individual to individual and in the same individual over time

Higher Risk of Celiac Disease After Elective Cesarean Delivery

Risk of celiac disease after cesarean delivery.

	Matched controls (%)	Celiac disease (%)	Odds ratio; 95% CI OR	P-value	Adjusted odds ratio*, 95% CI AOR	P-value
Cesarean delivery	5,766/53,887 (10.7)	1,299/11,749 (11.1)	1.04; 0.98-1.10	0.232	1.06; 0.99-1.13	0.074

Hypothesis

Combination of introduction of gluten into the diet and particular microbiota composition of infants genetically at risk for CD activates specific metabolic pathways that can contribute to the loss of tolerance to gluten and to the onset of autoimmunity, as reflected by specific metabolomic phenotypes
